ASPECTS REGARDING THE CUESTA LANDFORMS FROM THE CENTRAL MOLDAVIAN PLATEAU. Cuestas are the most widespread structural landforms in the Central Moldavian Plateau, their orientation varying broadly from northeast to west. I. Ioniță [5] demonstrates that this fact is explainable by considering a double system of stratigraphic slopes, a main declivity oriented southwards and a secondary one eastwards. This study attempts to differentiate among the generally north-facing cuestas from the west-facing ones, by comparing several morphometrical indices and also to investigate the degree of morphometrical asymmetry associated to the cuesta landforms.
